Executive summary

This report describes the methodologies applied to determine the contribution of African dust and sea salt to the 2011 ambient airborne PM_{10} mass concentration in Gibraltar. It summarises the impact of this quantification on Gibraltar's compliance (natural contributions can be removed from the measured concentrations for compliance assessment) with the 2011 daily and annual mean PM_{10} Limit Value (LV) as specified in the European Commission's Air Quality Directive (AQD). The annual mean PM_{10} LV is 40 µg m⁻³ and the daily mean PM_{10} LV is 50 µg m⁻³ not to be exceeded on more than 35 days in a calendar year.

The two natural sources of relevance to Gibraltar are (1) African dust, and (2) sea salt. The African dust component of the PM_{10} mass concentration in Gibraltar has been quantified since 2006, however daily measurements to determine the contribution of sea salt to the PM_{10} only commenced in Gibraltar in April 2011, allowing a quantification of both sources for the first time in 2011.

The PM_{10} mass concentration is measured at Bleak House (classified under the Directive as an urban background station) and Rosia Road (classified under the Directive as an urban traffic station). In 2011, Rosia Road exceeded the PM_{10} daily LV but not the annual mean LV. Bleak House did not exceed the daily mean or annual mean LV. Table E1 shows summary statistics for both monitoring stations. The table shows the original, uncorrected PM_{10} mass concentrations from both air quality monitoring stations in Gibraltar, and the corrected mass concentration based on the quantification of African dust and then the correction for African dust and sea salt together.

Table E1:2011 summary of results of natural correction for compliance with AQD
LVs.

	(Rosia Road (urban traffic)		Bleak House an background)
	Annual mean (µg m ⁻³)	Number of exceedances* of the daily mean PM ₁₀ LV	Annual mean (µg m⁻³)	Number of exceedances* daily mean PM ₁₀ LV
Uncorrected PM ₁₀ mass concentration	38	44	30	11
Corrected PM ₁₀ mass concentration after application of African dust correction factor	36	30	28	2
Corrected PM ₁₀ mass concentration after application of African dust <i>and</i> sea salt correction factor	34	25	**	**

* 35 permissible exceedances per annum.

** daily mean PM₁₀ sea salt mass fraction not measured at Bleak House.

Table E1 shows that Gibraltar was compliant with the annual mean PM_{10} LV in 2011 before the natural correction was applied, but there were more than the 35 exceedances of the daily mean PM_{10} LV exceedances (44 in total). After the natural correction (for both African dust and sea salt) was applied the number of exceedances of the daily mean PM_{10} LV was 25, indicating compliance once natural contributions to the PM_{10} mass concentration in Gibraltar were accounted for.

1 Introduction

This report describes the methodologies applied to determine the contribution of African dust and sea salt to the 2011 ambient airborne PM_{10} (hereafter simply referred to as PM_{10}) mass concentration in Gibraltar. It summarises the impact of this quantification on Gibraltar's compliance with the 2011 daily and annual mean PM₁₀ LV (Limit Value) as specified in the Air Quality Directive (AQD)¹.

European Directive 1999/30/EC² specifies that Member States are obliged to implement action plans where the LVs for air pollutants, namely sulphur dioxide (SO₂), nitrogen dioxide (NO_2) and oxides of nitrogen (NO_X) , particulate matter (PM_{10}) and lead in ambient air, are exceeded due to causes other than natural events. In July 2010 the AQD superseded the Framework Directive (96/62/EC) and the first three Daughter Directives (1999/30/EC, 2000/69/EC, and 2002/3/EC). As part of the AQD, the Commission issued further guidance for assessing and reporting of air pollutant concentrations where natural sources contribute to the exceedance of air pollutant LVs. Member States are required to inform the Commission in instances where natural events result in air pollutant concentrations that are significantly in excess of typical background concentrations. Member States are expected to provide justification to demonstrate that the measured exceedances were due to natural The mechanism for reporting concentrations to the Commission is the annual events. reporting questionnaire. The annual reporting questionnaire includes specific forms to allow the contribution from natural sources, and corrected PM₁₀ concentrations, adjusted for this natural component, to be reported. The two natural sources of relevance to Gibraltar are (1) African dust, and (2) sea salt.

The African dust component of the PM₁₀ mass concentration in Gibraltar has been quantified since 2006. A significant number of exceedances of the daily mean PM₁₀ LV measured in Gibraltar arise due to African dust events which affect the Iberian Peninsula as a whole. There is considerable year-to-year variability in the number of African dust events. Typically African dust events arise due to a combination of drought in North Africa and synoptic-scale (e.g., over a horizontal scale of 1000 km) meteorology.

Gibraltar is a peninsula and therefore the impact of sea salt on the PM₁₀ mass concentration is likely to be significant under certain meteorological conditions. Synoptic scale meteorological events and sea state contribute to the generation of sea spray and therefore the contribution of sea salt to the PM₁₀ mass concentration in Gibraltar. Daily measurements to determine the contribution of sea salt to the PM_{10} mass concentration commenced in Gibraltar on the 8th April 2011. This allowed a daily correction for 2011 which captures the day-to-day variation in the contribution of sea salt to the PM₁₀ mass concentration.

In 2011 the Gibraltar Air Quality Monitoring Network recorded 44 exceedances (based on measurements taken at the Rosia Road air quality monitoring station³) of the daily mean PM_{10} LV (50 µg m⁻³). The AQD permits up to 35 exceedances of the LV per calendar year. This exercise is therefore an essential assessment to demonstrate compliance (or otherwise) after accounting for the contribution made by natural sources to the daily mean PM₁₀ mass concentration.

The impact of both natural African dust and sea salt was assessed in 2011. In order to provide a complete PM_{10} daily data set corrected for both natural sources it has been necessary to undertake the African dust quantification methodology prior to removing sea salt due to concerns that undertaking a sea salt correction first may affect the application of the prescribed African dust quantification methodology.

2 African dust

2.1 Method

This section presents the methodology used to determine the contribution of African dust events to the PM_{10} mass concentration in Gibraltar. The term "African dust correction factor" refers to the mass concentration of PM_{10} which was subtracted from the measured PM_{10} mass concentration to account for the contribution of African dust events to elevated PM_{10} mass concentrations in Gibraltar.

Overall, two forms of African dust correction are applied: the first to the measured daily mean PM_{10} mass concentration, the second to the annual mean PM_{10} mass concentration (determined from the daily mean measurements). The results of the 2011 African dust correction are presented here.

For the preparation of on-going mandatory reporting to the Commission, in-line with the Air Quality Directive (2008/50/EC), the Spanish authorities identified specific days in 2011 on which regional background PM_{10} mass concentrations across the Iberian Peninsula were significantly enhanced by African dust events⁴. These events are referred to as "African dust days" and were assessed using a qualitative methodology developed by Querol et al.⁵.

The method for identifying African dust days was discussed at the workshop "Contribution of natural sources to PM levels in Europe" organised by the Joint Research Council, Ispra in October 2006 and was reviewed in the subsequent workshop report⁶. The methodology was incorporated into Commission staff working paper establishing guidelines for demonstration and subtraction of exceedances attributable to natural sources under the Directive 2008/50/EC on ambient air quality and cleaner air for Europe⁷. For consistency, this approach has been adopted by Gibraltar for reporting exceedances of the daily and annual mean PM_{10} LV due to African dust events to the Commission.

2011 PM_{10} mass concentrations from the regional background stations across the Iberian Peninsula, as shown in Figure 1, were used to determine the regional background PM_{10} mass concentration using methodology developed by Escudero et al.⁸. This allowed the increase in the PM_{10} mass concentration in Gibraltar due to African dust events to be derived.

Historically, the absence of a single regional background station to be paired with Gibraltar meant that the regional background PM_{10} mass concentration was derived from several Spanish regional background stations (Figure 1). The methodology employed to calculate the regional background PM_{10} mass concentration, and subsequently the increase in the

PM₁₀ mass concentration due to African dust events from multiple stations, was discussed in previous studies^{9,10,11}.

* station locations are approximated

Since 2009, the PM_{10} mass concentration measurements from the regional background monitoring station at Alcornocales were made available by the Spanish Government for the purposes of quantifying the increase in the daily mean PM_{10} mass concentration in Gibraltar due to African dust events. The regional background PM_{10} monitoring station at Alcornocales is located significantly closer to Gibraltar than the other Spanish regional background monitoring stations shown in Figure 1. Given its proximity to Gibraltar, the African dust correction factor at the Alcornocales air quality monitoring station will be more representative of the situation in Gibraltar. For this reason Alcornocales continues to be used as the regional background monitoring station paired with the Gibraltar Air Quality Network stations in order to account for the impact of African dust.

The number of days allocated as "African dust days" refers to the total number of days for which the African dust correction factor was applied to the 2011 daily mean PM_{10} mass concentration measured in Gibraltar. These do not necessarily correspond to the daily exceedances of the daily mean PM_{10} LV measured in Gibraltar. The aim of this exercise is not just to correct exceedance days, but to correct the daily mean PM_{10} mass concentration on ANY day on which there was a significant contribution to the measured PM_{10} mass concentration due to an African dust event. This approach allows for the calculation of a 2011 corrected annual mean PM_{10} mass concentration for Gibraltar for comparison with the annual PM_{10} LV stated in the Directive in addition to the daily assessment.

The daily regional background measured PM_{10} mass concentration for Alcornocales was calculated by initially removing the African dust days from the PM_{10} mass concentration measurements. A moving 30th percentile across a 30 day period centred on the day for which the calculation was being made (i.e., the day of the calculation is day 15 of the 30 day

⁹ Kent, A.J.: 2006 African dust quantification. <u>http://www.gibraltarairguality.gi/documents/Gib_natural_quantification_2006_v2.pdf</u>

¹¹ Kent, A.J.: 2008 African dust quantification. http://www.gibraltarairquality.gi/documents/Gib_natural_quantification_2008_v1.pdf

period) was derived. This calculated value provides a measure of the regional background PM_{10} mass concentration in the absence of African dust events.

The calculated regional background PM_{10} mass concentration was subtracted from the daily mean PM_{10} mass concentration measured at the regional background monitoring station (Alcornocales) to provide an African dust increment for that day. On occasions when negative increments were calculated these values were omitted from further calculations. The African dust increment on each day is subtracted from the daily mean PM_{10} concentration measured at the station being corrected (Rosia Road). This results in series of "corrected" daily mean PM_{10} concentrations from which the number of daily exceedances and annual mean can be re-calculated for assessment against the LV stated in the Directive.

The use of the measurements from the Alcornocales regional background PM_{10} monitoring station made accounting for the contribution of African dust events to the PM_{10} mass concentration in Gibraltar simpler and more robust. This approach avoids the need to establish a regional background PM_{10} mass concentration based on a range of measurements taken across a wide spatial extent as used in 2006-08^{9,10,11}. It is unclear whether the PM_{10} mass concentration from the Alcornocales station will be available in future years. Therefore it may be necessary to revert to the previous approach in future.

2.2 African dust quantification results

The results of the application of the African dust correction factor to the 2011 daily mean PM_{10} mass concentrations measured at the Rosia Road and Bleak House¹² monitoring stations are summarised below. Table 1 provides the number of exceedances of the daily mean PM_{10} LV before and after application of the correction. Table 2 summarises the annual mean PM_{10} mass concentration at the two air quality monitoring stations in Gibraltar before and after application.

Table 1: Number of exceedances of the daily mean PM_{10} LV of 50 µg m⁻³ (35 permissible exceedances per year) in 2011.

		Bleak House (background)
Number of exceedances based on the uncorrected PM_{10} mass concentration	44	11
Number of exceedances based on the corrected PM ₁₀ mass concentration after application of the African dust correction factor	30	2

Table 2: Summary of the 2011 annual mean PM_{10} mass concentration (annual mean PM_{10} LV = 40 µg m⁻³) (µg m⁻³).

		Bleak House (background)
Uncorrected PM ₁₀ mass concentration	39	30
Corrected PM_{10} mass concentration after application of the African dust correction factor	36	28

Table 1 demonstrates that the application of African dust correction to the daily mean PM_{10} mass concentration measurements from the Rosia Road monitoring station reduced the number of exceedances of the daily mean PM_{10} LV from 44 to 30. The resultant number of exceedances of the daily mean PM_{10} LV was below the 35 exceedances permitted by the Directive. Application of the African dust correction has therefore resulted in compliance with

¹² Station information can be found at <u>http://www.gibraltarairquality.gi/index.php?lg=&t_action=info&station_id=GIB2&t=3&map=</u>

the Directive for the daily metric even before further correction to account for sea salt contribution.

The 2011 annual mean PM_{10} mass concentration from the Rosia Road monitoring station was below the annual mean PM_{10} LV prior to the application of the African dust correction. Table 2 shows that the annual mean PM_{10} mass concentration after the application of African dust correction factor was 36 µg m⁻³.

In 2011, neither the daily mean PM_{10} LV or the annual mean PM_{10} LV were exceeded at the Bleak House monitoring station prior to the application of the African dust correction.

The African dust quantification and correction methodology has demonstrated that Gibraltar achieved compliance with the both the daily and annual PM_{10} LVs specified in the AQD in 2011. In order to account completely for natural sources, a further correction can be made to account for the contribution to measured concentrations from sea salt.

3 Sea salt

3.1 Overview

This section presents the methodology used to determine the contribution of sea salt in Gibraltar to the:

- Monthly mean total ambient airborne particulate matter (PM_x), and
- Daily mean PM₁₀ mass concentration,

Prior to 2010 no formal quantification of the contribution of sea salt to the daily or annual mean PM_{10} mass concentration was attempted in Gibraltar. Previous Spanish research¹³ indicated that sea salt contributed ~10% of the PM_{10} mass concentration (approximately 4 µg m⁻³) in the nearby Spanish town of La Línea de la Concepción, located just over the Gibraltar-Spain border.

The Commission staff working paper establishing guidelines for demonstration and subtraction of exceedances attributable to natural sources⁷ states that due to the episodic nature of sea salt emissions, accurate daily quantification is required in order to apply a correction to the daily mean PM_{10} mass concentration. Accounting for the sea salt contribution to the PM_{10} mass concentration, termed the PM_{10} sea salt mass fraction, reported in the Questionnaire also requires that the sea salt mass fraction be determined at each station reported.

The term "sea salt correction factor" refers to the daily PM_{10} sea salt mass fraction which was subtracted from the measured daily mean PM_{10} mass concentration. The sea salt mass fraction of PM_{10} was determined on a daily basis from 8th April 2011 onwards at the Rosia Road monitoring station. This correction factor was applied after the daily mean PM_{10} mass concentration was corrected for the influence of African dust. The results of the 2011 sea salt correction are presented here.

3.2 Sampling methodology

A comprehensive description of the methods used to quantify daily mean PM_{10} sea salt mass fraction in Gibraltar are contained within the "Measurement of sea salt aerosol in Gibraltar" report¹⁴. The report summarises the operation of a dedicated Partisol sampler to determine the daily mean PM_{10} sea salt mass fraction at the Rosia Road air quality monitoring station.

3.2.1 Partisol sampler

Measurement of the daily mean PM_{10} sea salt mass fraction was provided by a dedicated Thermo Scientific Partisol Plus 2025 Sequential Air Sampler installed at the Rosia Road monitoring station. Following exposure in the field, the exposed Partisol filters were returned to the laboratory. The water soluble components of the sampled particulate matter, including sea salt, were extracted from the sample filters by washing with deionised water. Ion

¹³ Querol, X., Alastuey, A., Moreno, T., Viana, M.M, Castillo, S., Pey, J., Rodriguez, S., Artinano, B., Salvador, P., Sanchez, M., Garcia Dos Santos, S., Herce Garraleta, M.D., Fernandez-Patier, R., Moreno-Grau, S., Negral, L., Minguillon, M.C., Monfort, E., Sanz, M.J., Palomo-Marin, R., Pinilla-Gil, E., Cuevas, E., de la Rosa, J., and Sanchez de la Campa, A.: Spatial and temporal variations in airborne particulate matter (PM₁₀ and PM_{2.5}) across Spain 1999-2005, Atmospheric Environment, 42(17), 3964-3979, doi: 10.1016/j.atmosenv.2006.10.071, 2006.
¹⁴ Lingard J. J. N. (2012). Measurement of sea salt aerosol in Gibraltar. <u>http://www.gibraltarairquality.gi/documents/Quantification of the contribution of sea salt final.pdf</u>

chromatography was used to determine the chloride (Cl⁻) and sodium (Na⁺) concentrations of the extracts. The daily mean mass concentration (µg m⁻³) of the chloride and sodium ions in the sampled particulate matter were calculated using Equation (1).

3.3 Calculation of the PM₁₀ sea salt mass fraction

Three methods are proposed⁷ for the calculation of the PM_X and PM_{10} sea salt mass fraction. These methods infer the PM₁₀ sea salt mass fraction from the measured chloride (Cl⁻) and/or sodium (Na⁺) concentrations. The proposed European method assumes that sea salt is composed only of NaCl and that all the chloride and sodium ions in the sampled PM₁₀ are associated with NaCl. Therefore, according to composition of sea salt, the PM_X and PM₁₀ sea salt mass fraction can be calculated thus:

Sea salt (μ g m⁻³) = $\frac{100}{55}$ x Cl⁻ = 1.8 x Cl⁻, or Equation (2)

Sea salt (μ g m⁻³) = $\frac{100}{30.6}$ x Na⁺ = 3.27 x Na⁺, or Equation (3)

Sea salt ($\mu g m^{-3}$) = (Na⁺ + Cl⁻) x 1.168. Equation (3)

Equation (2) was used to determine the PM_X and PM_{10} sea salt mass fraction. This is consistent with the UK approach¹⁵ where a scaling factor of 1.648¹⁶ is applied to infer the PM₁₀ sea salt mass fraction from chloride ion measurements, for pollutant mapping purposes. The use of chloride ion was potentially subject to positive and negative artefacts. The chloride concentration can be enhanced through the emission of hydrochloric acid (HCI) gas to the atmosphere from high-temperature combustion processes such as coal burning and incineration⁷. HCI emissions have decreased in recent years due to the reduction in the use of coal as a fuel in power generation and flue gas abatement measures.

This approach was adopted as PM₁₀ mass concentrations in Gibraltar were subject to enhancement due to African dust events: the horizontal transport of wind-blown dust from North Africa. One key component of wind-blown dust is sodium. Therefore the use of sodium to determine the PM_X and PM₁₀ sea salt mass fraction may have been subject to enhancement due to the presence of sodium in the sampled PM_X and PM₁₀ due to windblown dust.

Only the daily mean PM₁₀ sea salt mass fraction measurements from the Partisol sampler located at the Rosia Road monitoring station are used for the natural sources correction for compliance reporting, in accordance with the Guidance issued by the Commission⁷.

The contribution of natural sources (African dust and sea salt) to the PM₁₀ mass concentration measured at the Rosia Road monitoring station was achieved by firstly subtracting of the contribution to the daily mean PM₁₀ mass concentration from African dust. Secondly, the daily mean PM₁₀ sea salt mass fraction was subtracted to provide the daily and annual mean PM₁₀ mass concentration corrected for natural sources.

¹⁵ Brookes, D.M., Stedman, J.R., Grice, S.E., Kent, A.J., Walker, H.L., Cooke, S.L., Vincent, K.J., Lingard, J.J.N., Bush, T.J., and Abbott, J. (2011). UK modelling under the Air Quality Directive (2008/50/EC) for 2010 covering the following air quality pollutants: SO2, NOX, NO2, PM10, PM25, lead, benzene, CO, and ozone. Report to The Department for Environment, Food and Rural Affairs, Welsh Assembly Government, the Scottish Government and the Department of the Environment for Northern Ireland, AEAT/ENV/R/3215 Issue 1. http://uk-air 1204301513 AQD2010mapsrep master v0.pdf ¹⁶ The use of a scaling factor of 1.648 treats other alkali and alkaline metal components of sea salt (magnesium, calcium and potassium) as

sodium.

3.4 Sea salt quantification results

The results of the application of the African dust and sea salt correction factor to the 2011 daily mean PM_{10} mass concentrations measured at the Rosia Road and Bleak House¹⁷ monitoring stations are summarised below. The correction for the contribution from sea salt has been applied to daily PM_{10} mass concentrations already corrected for contributions from African dust. For clarity and comparison the results have been tabulated including the original measured concentrations, the corrected concentrations from African dust (as shown separately in the section above) and the concentrations that have been corrected to account for African dust and sea salt.

Table 3 provides the number of exceedances of the daily mean PM_{10} LV before and after application of the complete 2011 natural correction (African dust and sea salt). Table 4 summarises the annual mean PM_{10} mass concentration at the two air quality monitoring stations in Gibraltar before and after application of the complete 2011 natural correction (African dust and sea salt).

Table 3: Number of exceedances of the daily mean PM_{10} LV of 50 µg m⁻³ (35 permissible exceedances per year) in 2011.

	Rosia Road (roadside)	Bleak House (background)
Number of exceedances based on the uncorrected PM_{10} mass concentration	44	11
Number of exceedances based on the corrected PM ₁₀ mass concentration after application of the African dust correction factor	30	2
Number of exceedances based on the corrected PM_{10} mass concentration after application of the African dust correction factor <i>and</i> the sea salt correction factor	25	*

 * daily mean PM_{10} sea salt mass fraction not measured at Bleak House.

Table 4: Summary of the 2011 annual mean PM_{10} mass concentration (annual mean PM_{10} LV = 40 µg m⁻³) (µg m⁻³).

		Bleak House (background)
Uncorrected PM ₁₀ mass concentration	38	30
Corrected PM ₁₀ mass concentration after application of the African dust correction factor	36	28
Corrected PM ₁₀ mass concentration after application of the African dust correction factor <i>and</i> the sea salt correction factor	34	*

* daily mean PM₁₀ sea salt mass fraction not measured at Bleak House.

Table 3 shows that after African dust and sea salt were quantified and removed from measured concentrations at Rosia Road, the number of daily mean PM_{10} LV exceedances was 25, i.e., below the 35 permissible for compliance with the AQD. The number of days when the daily mean PM_{10} mass concentration measurements at Bleak House air quality monitoring station did not exceed the LV and were below the 35 exceedances permitted per year. The Bleak House measurements were corrected for African dust for completeness but could not be corrected further to account for sea salt due as the daily mean PM_{10} sea salt mass fraction was not measured here. It was not deemed necessary due to the likelihood of compliance in the absence of a formal correction.

¹⁷ Station information can be found at <u>http://www.gibraltarairquality.gi/index.php?lg=&t_action=info&station_id=GIB2&t=3&map=</u>

Table 4 shows that the annual mean PM_{10} mass concentrations measured at the Rosia Road and Bleak House air quality monitoring stations were compliant with the annual mean LV before accounting for the contribution of natural sources. The correction was applied for completeness. The daily mean PM_{10} mass concentrations from Bleak House could be not be corrected further, to account for sea salt, due to the absence of specific measurement equipment at the station as noted in the previous paragraph.

The African dust quantification and correction methodology has demonstrated that Gibraltar achieved compliance with the both the daily and annual PM_{10} LVs specified in the AQD in 2011. In order to account completely for natural sources, a further correction can be made to account for the contribution to measured concentrations from sea salt.

shows the variation in the number of exceedances of the daily mean PM_{10} LV in Gibraltar for the period 2005-11. The figure shows the effect of the application of the African dust correction for the full period, and the sea salt correction for 2011 to the daily mean PM_{10} mass concentration measurements from the Rosia Road monitoring station. The red dashed line represents the number of permissible daily exceedances of the daily mean PM_{10} LV (35 per year) allowed by the AQD. Figure 2 allows the effect of application of the African dust correction factor to be seen in the context of compliance with the AQD over several years, as well as the application of the sea salt correction this year.

Figure 3 shows the annual mean PM_{10} mass concentration measured at the Rosia Road monitoring station including and excluding African dust correction from 2005 to 2011, and the sea salt correction this year. The red dashed line represents the annual mean PM_{10} LV. In Figure 3, the blue line shows the uncorrected annual mean PM_{10} mass concentration whilst the darker green line shows the annual mean PM_{10} mass concentration after accounting for African dust. The lighter green line shows the additive effect of the sea salt correction factor in reducing the annual mean PM_{10} mass concentration from 2011 onwards.

Figure 2: Number of exceedances of the daily mean PM₁₀ LV measured at the Rosia Road monitoring station, 2005-11, before and after application of the African dust and sea salt (SS) correction.

Figure 3: Annual mean PM₁₀ mass concentration measured at the Rosia Road monitoring station, 2005-11, before and after application of the African dust and sea salt (SS) correction factor.

AEAT/ENV/R/3327 Issue 1

4 Summary

- Gibraltar was compliant in 2011 with the PM₁₀ LVs in the AQD after natural sources were quantified and removed from daily mean PM₁₀ mass concentrations at both Rosia Road and Bleak House monitoring stations.
- The annual mean PM₁₀ LV was not exceeded at either air quality monitoring station in Gibraltar in 2011.
- The daily mean PM_{10} LV was not exceeded on more than 35 days at Bleak House in 2011.
- Application of African dust correction to the daily mean PM₁₀ mass concentration measurements from the Rosia Road monitoring station reduced the number of exceedances of the daily mean PM₁₀ LV from 44 to 30, i.e., resulting in compliance with the AQD before even the application of the sea salt correction.
- Application of African dust correction to the annual mean PM₁₀ mass concentration measurements from the Rosia Road air quality monitoring station reduced the annual mean concentration from 38 μg m⁻³ to 36 μg m⁻³, i.e., resulting in compliance with the AQD before application of the sea salt correction.
- The additional application of the sea salt correction resulted in 25 exceedances of the daily mean PM₁₀ LV at Rosia Road air quality monitoring station. This is well below the 35 permissible under the AQD. The sea salt correction resulted in an annual mean PM₁₀ concentration of 34 µg m⁻³ at the Rosia Road air quality monitoring station indicating compliance once natural contributions to the PM₁₀ mass concentration in Gibraltar were accounted for.
